

## 2023 T1

Q2)

**Proof.** Suppose  $0 \leq x \leq \sqrt{\frac{36}{17}}$ . Notice that the Maclaurin series of  $f$  is given by:

$$f(x) = \sum_{k=0}^{\infty} A_k x^{2k+1}$$

**Solution:**

First, consider that the Maclaurin series of  $e^x$  :

$$\begin{aligned} e^x &= \sum_{k=0}^{\infty} \frac{x^k}{k!} \\ e^{\frac{-17t^2}{12}+7} &= e^7 \sum_{k=0}^{\infty} \frac{\left(-\frac{17t^2}{12}\right)^k}{k!} \\ &= e^7 \sum \int_0^x \frac{\left(-\frac{17}{12}\right)^k t^{2k}}{k!} dt \\ &= e^7 \sum \frac{x^{2k+1} \left(-\frac{17}{12}\right)^k}{(2k+1)k!} dt \end{aligned}$$

therefore,  $A_k$  is given by:

$$\frac{\left(-\frac{17}{12}\right)^k e^7}{(2k+1)k!}$$

An alternate solution (Thanks to amber on CSESoc Discord):

Maple has a function that allows us to efficiently find this using:

`convert(integral, FormalPowerSeries)` (This is super useful!)

*Continuing on with the question:*

By Taylor's theorem with the Lagrange formula for the remainder, there exists some  $0 \leq c \leq x$  such that:

$$\begin{aligned} |f(x) - P_3(x)| &= |R_4(x)| = \frac{f^{(4)}(c)x^4}{4!} \\ &= Bx^4 e^{-17/12c^2+7} \end{aligned}$$

Find B.

**Solution:**

We've been given the 4th derivative in the maple output at the beginning of the question:

$$289/12*\exp(7)*x*\exp(-17/12*x^2)-4913/216*\exp(7)*x^3*\exp(-17/12*x^2)$$

We can then remove all the  $\exp(7)$  and  $\exp(-17/12x^2)$ , and the sub in  $x$  for  $c$ , to find B.

*Continuing on with the question:*

However, notice that for such  $c$  we must have

$$0 \leq \left| 3 - \frac{17}{6}c^2 \right| \leq 3$$
$$0 \leq \exp\left(-\frac{17}{12}c^2 + 7\right) \leq \exp(7)$$

**Solution (Thanks to one eight seven on CSESOC discord):**

For  $3 - \frac{17}{6}c^2$ , we see that it is constantly decreasing, and therefore, we simply check the endpoints.

It is seen that 0 produces the maximum value, which is 3.

For  $\exp\left(-\frac{17}{12}c^2 + 7\right)$ , it is similar in the fact that it is monotonically decreasing. Therefore, check the end points once more, and we find that  $\exp(7)$  is the maximum

Note:  $0 \leq x \leq \sqrt{\frac{36}{17}}$ . Therefore  $0 \leq c \leq x$ .

**Q3)**

a) Consider the different trigonometric identities until they fit:

$$\begin{aligned}\cos^2 x + \sin^2 x &= 1 \\ 1 + \tan^2 x &= \sec^2 x \\ \cosh^2 x - \sinh^2 x &= 1 \\ 1 - \tanh^2 x &= \operatorname{sech}^2 x\end{aligned}$$

b) Same as above, but with a side note:

$$1 - \tanh^2 x = \operatorname{sech}^2 x$$

Don't be fooled into thinking we can use the negative tanh as a substitution!

c) Same as above, we instead of  $\tan x$ , we end up using  $\cot x$ , as well as a  $\operatorname{cosech}^x$  identity.

Q4)

a)  $T_1$  is a linear transformation

Consider if the zero vector exists within the linear transformation.  
 $\langle 0.a, 0.b \rangle = \langle 0, 0 \rangle$ , therefore, true.

Consider if the linear transformation is closed under addition.

Two arbitrary vectors,  $x$  and  $y$ , in  $R^3$ , are applied to the linear transformation:

$$T(x) + T(y) = \langle x.a, x.b \rangle + \langle y.a, y.b \rangle = \langle x.a + y.a, x.b + y.b \rangle$$

$$= \langle a.(x + y), b.(x + y) \rangle$$

$$= T(x + y)$$

Consider the scalar multiplication of an arbitrary vector within the linear transformation:

$$T(cx) = \langle (cx).a, (cx).b \rangle$$

$$= c.\langle x.a, x.b \rangle$$

b)  $T_2$  is not a linear transformation

Consider the zero element:

$$\text{sqrt}(0 + 0) = 0$$

Consider closure under addition with two arbitrary vectors  $a$  and  $b$  in  $R^2$ .

$$T(a) + T(b) = \text{sqrt}(8*a1^2 + 6*a2^2) + \text{sqrt}(8*b1^2 + 6*b2^2)$$

$$T(a + b) = \text{sqrt}(8*(a1 + b1)^2 + 6*(a2 + b2)^2)$$

Therefore, not closed under addition

c)  $T_3$  is not a linear transformation

$$T(p(x)) = p(x) + 5x^2 - 2x$$

Consider the existence of zero:

$$p(0) + 5(0)^2 - 2(0)$$

$= p(0)$ , not guaranteed to be zero.

**Q4)**

You must check both the standard eigenvectors of multiple 1, and also, the fact that there

can be a linear combination of the vectors.

A matrix  $A$  has eigenvalues and eigenvectors

$$\lambda = 9, \quad \mathbf{v} = s \begin{pmatrix} 1 \\ 0 \\ 3 \end{pmatrix} + t \begin{pmatrix} -2 \\ 1 \\ 2 \end{pmatrix} \quad \text{and} \quad \lambda = -1, \quad \mathbf{v} = u \begin{pmatrix} 1 \\ 3 \\ -1 \end{pmatrix}.$$

Which of the following give a correct diagonalisation  $A = MDM^{-1}$ ? [Select all correct answers.]

**Multiple selection advice.** In a multiple selection question, marks are deducted for incorrect selections (but you cannot get less than zero marks). You are advised to only select options that you are sure about.

☒  $D = \begin{pmatrix} 9 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad M = \begin{pmatrix} 1 & 2 & 3 \\ 0 & 1 & 9 \\ 3 & 14 & -3 \end{pmatrix}.$

☒  $D = \begin{pmatrix} 9 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 9 \end{pmatrix}, \quad M = \begin{pmatrix} -2 & 1 & 1 \\ 1 & 3 & 0 \\ 2 & -1 & 3 \end{pmatrix}.$

☐  $D = \begin{pmatrix} 9 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad M = \begin{pmatrix} 1 & 2 & 1 \\ 0 & 0 & 3 \\ 3 & 6 & -1 \end{pmatrix}.$

☐  $D = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & 9 \end{pmatrix}, \quad M = \begin{pmatrix} 1 & -2 & 1 \\ 0 & 1 & 3 \\ 3 & 2 & -1 \end{pmatrix}.$

☒  $D = \begin{pmatrix} 9 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad M = \begin{pmatrix} 1 & -2 & 1 \\ 0 & 1 & 3 \\ 3 & 2 & -1 \end{pmatrix}.$

☐ none of the above,  $A$  is not diagonalisable.

Q6)

Three axioms are contained within vector spaces:

a) Addition: Given two elements  $x, y$  in  $X$ , one can form the sum  $x + y$ , which is also an element of  $X$ .

b) Inverse: Given an element  $x$  in  $X$ , one can form the inverse  $-x$ , which is also an element of  $X$ .

c) Scalar multiplication: Given an element  $x$  in  $X$  and a real number  $c$ , one can form the product  $cx$ , which is also an element of  $X$ .

1. For all vectors  $\mathbf{u}$  and  $\mathbf{v}$  and all scalars  $\lambda$ , we have  $\lambda(\mathbf{u} + \mathbf{v}) = \lambda\mathbf{u} + \lambda\mathbf{v}$   
This is axiomatic
2. There exists a vector  $\mathbf{0}$  such that for all vectors  $\mathbf{v}$ , we have  $\mathbf{0}\mathbf{v} = \mathbf{0}$   
This is not true, as it refers to the **vector**  $\mathbf{0}$ .
3. For all vectors  $\mathbf{u}$  and  $\mathbf{v}$  and  $\mathbf{w}$ , we have  $(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{v} + (\mathbf{w} + \mathbf{u})$   
This is not axiomatic, but it can be proved through axioms
4. For any vector  $\mathbf{v}$ , if  $0$  is the zero scalar and  $\mathbf{0}$  is the zero vector, then  $0\mathbf{v} = \mathbf{0}$ .  
This is not axiomatic, but it can be proved through axioms
5. For all vectors  $\mathbf{u}$  and  $\mathbf{v}$  and all scalars  $\lambda$  and  $\mu$ , we have  $(\lambda + \mu)(\mathbf{u} + \mathbf{v}) = \lambda\mathbf{u} + \lambda\mathbf{v}$   
This is false, and breaks the distributive axiom
6. For all vectors  $\mathbf{u}$  and  $\mathbf{v}$  and all scalars  $\lambda$ , if  $\lambda\mathbf{u} = \lambda\mathbf{v}$  then  $\mathbf{u} = \mathbf{v}$ .  
This is visibly not true.

**Q7)**

a) Consider that the matrix is in form:

$$\begin{pmatrix} a & b \\ 0 & c \end{pmatrix}$$

Consider that  $a, b, c \in \{0, 1, 2, \dots, 43\}$ . Therefore, there are  $44 \cdot 44 \cdot 44$ .

b) Give the number of matrices in  $T$  that are not diagonalisable

A matrix in the triangular form that this question poses is not diagonalisable when:

$$\begin{pmatrix} a & b \\ 0 & a \end{pmatrix}$$

However, it must be taken into consideration that  $b \neq 0$  for this to be true. (As the zero matrix is diagonalisable)

Hence, this comes out to be  $43 \cdot 44$ .

c) Simply put the result of b on a, to find the probability of getting a diagonalisable matrix.
